-----  
How much power does a data center cabinet use?

Almost every data center has some variation of power among cabinets. It is common to find cabinets operating from 50 watts (a network switch with patch panels) up to 30 kW (fully loaded high performance blade servers). This represents a range of 60 to 1in power consumption.

How much power is allowed per cabinet?

The design target average power per cabinet is 5 kW. The peak power allowed in any cabinet is 12.5 kW as long as the pod power does not exceed 50 kW for all 12 cabinets combined. The total indoor space required by this design is 25,320 ft<sup>2</sup> (2,352 m<sup>2</sup>).

Does a data center have a watt capacity?

A data center also has an IT load power capacity and a cooling capacity(which ideally should be the same),and it has an IT space capacity (cabinets or square feet). The ratio of the watt capacity to the space is the design density (for this discussion,we assume the power,cooling,and space are all built out to maximum design capacity).

How much power does a mixed use data center use?

The vast majority of mixed use data centers within organizations exhibit average values in the range of 4 kW to 8 kW per cabinet. However,in general,the existing average values in a data center are not a good predictor of future values. Consolidation,standardization,new server technology,and virtualization are driving up per cabinet densities.

Other considerations are: Power requirements (clean supply and/or UPS) Earthing Ventilation/Air Conditioning/Cooling Lighting Raised access floor If a location houses one or ...
